PING

OWNER'S MANUAL

OWNER'S MANUAL

FIREDIES PRODUCTIONS · OXFORD · FD-2026-PG-V1.0

Know before the game tells you.

Ping puts your connection on your deck—live latency to any server you care about, your real traffic in and out, and a full speed test on one press. Green when it's healthy, red when it isn't, and you see it happening rather than finding out mid-fight.

Nothing is guessed. If a server can't be reached the face says so instead of showing you a stale number that looks fine.

02 QUICK START

1. Drag Ping (under Ping) onto any key or dial.
2. It's already live against a starter list—Google, Cloudflare, GitHub.
3. Open its settings and put your own server in. A full URL or just a domain: **google.com** works.

03 THE FOUR

Ping	Live latency to whichever server you're watching, tinted by health.
Download	Your real download traffic, live, in MB/s. Press to run a capacity test.
Upload	The same going out—useful the moment you start streaming.
Speed Test	Ping, download and upload in one, powered by Cloudflare. Press to run.

All four work as a **key** or as a **dial**.

One list, every control.

Add a server once and it's everywhere—the list is shared by every Ping control on your deck, so you're never maintaining it twice.

Turn the dial	Steps through your servers. On a key, press does the same.
---------------	--

Tap the sides	On a touch strip, left goes back and right goes forward.
---------------	--

Press the dial	Takes a fresh reading right now, without waiting for the next check.
----------------	--

Press and hold	Jumps straight back to the first server in your list—your home.
----------------	---

Each server gets an icon automatically: a bundled brand mark if we have one (29 are bundled, and 22 addresses are recognised on sight without asking the network), otherwise the site's own icon fetched live. Click a server's **icon chip** to override it with any emoji or a picture of your own.

05 DETECT MY SERVER

You usually don't know the address of the game server you're actually on. **Detect my server** looks at what your machine is genuinely connected to and offers you the candidates, so you can watch the real thing instead of the publisher's front page.

It reads TCP connections. Many games carry gameplay over UDP, and those will not appear—the panel says so rather than pretending the list is complete.

06 FOUR STYLES

Color bar	The number plus a bar underneath, coloured by health.
-----------	---

B & W	Monochrome. The bar is brightest when your ping is best, and darkens as latency climbs.
-------	---

Clean	Just the number, large—and the number itself carries the colour.
-------	--

History	The bar becomes a live graph. Oldest on the left, now on the right.
---------	---

07 WHAT COUNTS AS GOOD

Out of the box: green under 100 ms, red over 550 ms, travelling through amber between them. Both numbers are yours—a competitive shooter and a video call have very different ideas of "fine".

A server that answers nothing at all counts as down after about **six seconds**—two waiting for the ping, four more for the fallback. You can pick your own calm, working and busy colours, or turn the health colouring off and have one fixed colour instead.

08 THE TRAFFIC METERS

Download and Upload show what is *actually moving* right now, not what your line could do in theory. They add up every network adapter, so with a VPN running you may see the same traffic counted twice. Two choices worth knowing about:

- **MB/s or Mbps.** Megabytes per second is what a download shows you; megabits per second is what your provider sold you. They differ by a factor of eight, which is why one always looks disappointing. Pick whichever you think in.
- **Colour runs the other way here.** On Ping a big number is bad; on the meters it isn't—so out of the box the meters read calm green when the line is quiet and climb through amber to red as it fills up. Tick *reverse it: slow = red, fast = green* if you'd rather fast was the green one; the three colours are yours either way.

09 THE SPEED TEST

Powered by Cloudflare, the same service behind a large share of the web—so the test runs against real infrastructure near you rather than a server we chose to flatter the result.

On a dial, turn to cycle the four views and **press** to run. On a key, **press** runs it.

10 ALERTS AND FEEL

- **Chime when the connection drops**—eight sounds included, or point it at a file of your own, with its own volume.
- **Tactile click on press**, so a key feels like it did something. Also yours to change or switch off.
- **Show the IP** of whatever you're pinging, or hide it for a cleaner face. On a key it takes the bar's place rather than crowding it.
- **Show the MS unit**, or drop it and let the number have the whole face.
- **Number aligned** left, middle or right on dials—left by default, so it lines up with the icon and the bar. Keys are always centred.
- **Every label renders in your own script.** Japanese, Chinese, Korean, Arabic, Hindi, Thai, Hebrew and more.

We'd rather tell you now.

- **It is a real ping first, and a fallback second.** Ping asks Windows to send an actual ICMP echo, the same thing the ping command does. Plenty of hosts refuse ICMP, so when there is no reply it opens a TCP connection to the port instead and times that. Both are honest measurements; the TCP one usually reads a few milliseconds higher because a connection is more work than an echo.
- **UDP game servers can't be detected.** See *Detect my server*. If your game carries play over UDP, watch its login or matchmaking host instead—it usually sits in the same datacentre.
- **A speed test is a snapshot.** Run it while a download is going and it will read low, correctly. The Download and Upload meters show your live traffic, which is the better number to watch.
- **Server icons are fetched from the internet** the first time a server is seen—brand marks from a public icon service, otherwise the site's own favicon. Bundled ones need no network at all. There's no analytics and no account—though the lookup does have to name the domain to the icon service it asks, so set your own icon on anything you'd rather keep here.
- **Windows only, for now.**

12 IF SOMETHING LOOKS WRONG

The number is a dash	That server didn't answer inside 4 seconds. It is down, blocking us, or the address is wrong.
Higher than my game shows	That host is refusing ICMP, so the reading is a TCP connection instead. Slightly higher, and it tracks the same movement. If <i>every</i> server reads high, it's probably that Windows isn't in English—we read Windows' own ping output and only understand the English wording, so we fall back to TCP everywhere.
A server has no icon	It has no bundled mark and no reachable favicon. Give it an emoji or your own picture from its icon chip.
Speed test reads low	Something else is using the line. That is the honest number—watch the live meters instead.
